## Crystal Structures of Protic Ionic Liquids and their hydrates

Thursday, 25 November 2021 18:02 (1 minute)

Protic Ionic Liquids (PILs) are a class of tailorable solvents made up of fused salts with melting points below 100 °C, which are formed through a Brønsted acid-base reaction involving proton exchange[1]. These solvents have applications as lubricants, electrolytes, and many other uses[2]. Although they are quite similar to molten salts, their crystal structures have not been explored in-depth, with only ethylammonium nitrate (EAN) having a reported crystal structure[3, 4]. Ten alkylammonium-based protic ionic liquids at both neat (<1 wt% water) and 90 mol% PIL, 10 mol% water concentrations were selected. Diffraction patterns were collected at the Australian Synchrotron ANSTO while attempting to crystallise the samples by cooling to 120 K. Five samples crystallised (3 neat, 2 dilute), where the temperature of the system was then increased at a rate of 6 K/min to room temperature. From these patterns we have identified a number of crystal phases, identifying their stability ranges and lattice constant variation from 120 K to room temperature.

Presenter Gender

Man

Do you wish to take part in the Student Poster Slam

No

Condition of submission

Yes

Students Only - Are you interested in AINSE student funding

Yes

Level of Expertise

Student

Pronouns

He/Him

Which facility did you use for your research

Australian Synchrotron

Primary author: HASSETT, Michael (RMIT University)

Co-authors: BRAND, Helen (Australian Synchrotron); BINNS, Jack (RMIT University); MARTIN, Andrew (RMIT University); GREAVES, Tamar (RMIT University)

Presenter: HASSETT, Michael (RMIT University)

Session Classification: Poster Session

Track Classification: Chemistry, Soft Matter & Crystallography
