Characterisation of Ionic Liquids and Their Ability to Stabilise Proteins

Wednesday, 24 November 2021 16:50 (15 minutes)

Proteins are an important part of biotechnology and can be utilised for a range of applications and industries¹. But the stability and solubility of the protein is often a limiting factor, so ionic liquids (ILs) have been tested as an alternative solvent due to their wide scope and tailorable properties. They are reported to increase protein activity², solubility, long term and thermal stability. However, the relationship between the structure of an IL and how it interacts with proteins in solution is unknown.

In this study 52 ammonium based ILs and 14 common salts were prepared with HEWL and human lysozyme. Physicochemical, and thermal properties of the neat ILs were characterised, while SAXS was used to characterise protein stability. High concentrations of IL (>50 mol%) were often not conducive with the native structure of the protein, while lower concentrations (1-10 mol%) can support native protein structures with minimal to no aggregation. It was also found that additional alkyl chains on the cation, and the presence of hydroxyl groups reduced lysozyme's radius of gyration, preserving its native structure.
