

Powder diffraction

Qinfen Gu

Anita D'Angelo

Liam Tan

Outline

- Basic theory of Powder diffraction
- Instrumentation & facilities
- Highlight of case studies
- Beamline guide and access

Why powder diffraction?

- Real materials are often powders
- Easy sample preparation
- No need to rotate the sample (simpler sample environments)
- Fast data collection – time-resolved experiments
- Multiple phases/fingerprinting

What is a powder?

- By “powder” we mean a polycrystalline material.
- Much of the world is crystalline but things rarely exist as large single crystals.
- Metals are typically polycrystalline and diffract like a powder.
- Small crystals are called “crystallites”

Metal grains are tiny crystals

Grain boundary in gold (STEM image)

Powder diffraction

- ❖ Unit cell parameters and space group determination
- ❖ Qualitative phase identification for single and multiple phases
- ❖ Quantitative phase identification
- ❖ Structure solution and refinement
- ❖ Crystallite size and strain from peak profiles
- ❖ Time-resolved and *in-situ* experiments
- ❖ Physical properties such as thermal expansion and compressibility

Powder diffraction

Graphite

Diamond

Diffraction - Theory

- Crystal lattices have regularly-spaced planes of atoms
- X-Rays (and some neutrons) have wavelengths close to these plane spacings ($\lambda \sim 1 \text{ \AA} = 10^{-10} \text{ m}$).

- We only observe diffracted X-rays when Bragg's law is satisfied.

n is an integer

λ is the X-ray wavelength

d is the inter-planar spacing

2θ is the diffraction angle

“Powder” Diffraction – Demo

An ideal powder has a very large number of randomly oriented crystallites

Powder Diffraction – Theory

- An ideal powder has a very large number of randomly oriented crystallites.
- For each particular crystal plane spacing (hkl), there will be many crystallites with the correct orientation to satisfy the Bragg diffraction condition.

Imperfect powders

2D area detector images

Very grainy powder

Better, but not ideal

Texture

- On the other hand, “texture” can tell us about the non-random orientation of crystallites/grains in our materials.
- XRD is a powerful technique for investigating strain (residual stresses) in materials.
- Can provide information about the directionality of strain.

Samples - capillary

- Glass or quartz capillaries. Sapphire for special uses.
- Diameter typically 0.2–1.0 mm, 0.01 mm wall thickness.
- Capillaries can be sealed to keep air/moisture out or solvents in.
- Tricky to load. Takes practice.

Instrumentation – Bragg–Brentano geometry

- “Flat plate” or “reflection” geometry.
- Large area of sample illuminated.
- Low beam absorption, higher peak intensity.
- Risk of preferred orientation.
- Sample spinning is commonly used.

Samples – flat plate

- Ideal crystallite size is 1-10 μm .
- Smooth and flat surface, but polishing not required.
- Correct sample height
- Zero diffraction plates (ZDPs) for small samples.

Instrumentation – X-ray generator

- A Cu target (yielding Cu $K\alpha$ X-rays) is the most common radiation source for powder diffraction.
- $K\beta$ wavelengths are excluded by a filter (e.g. Ni filters out Cu $K\beta$).
- Some instruments have a monochromator to select $K\alpha_1$ wavelength only.
- Shorter wavelengths have higher energy and are absorbed less but bring diffraction peaks closer together.

Element	$K\alpha_1$ (Å)	$K\alpha_2$ (Å)	$K\beta$ (Å)
Cr	2.2898	2.2937	2.0849
Co	1.7890	1.7929	1.6208
Cu	1.5406	1.5444	1.3923
Mo	0.7093	0.7136	0.6323
Ag	0.5594	0.5638	0.4971

X-ray fluorescence

- Elements in the sample may emit fluorescent X-rays (e.g. Co, Fe fluoresce strongly when illuminated by Cu $K\alpha$ X-rays).
- If the emitted X-rays are close in energy to the incident wavelength they will be detected. This manifests as an elevated background and gives a reduced peak-to-background ratio.
- Some solutions:
 - Use a different wavelength if available.
 - Change the detector energy threshold.

19 K Potassium	20 Ca Calcium	21 Sc Scandium	22 Ti Titanium	23 V Vanadium	24 Cr Chromium	25 Mn Manganese	26 Fe Iron	27 Co Cobalt	28 Ni Nickel	29 Cu Copper	30 Zn Zinc	31 Ga Gallium
37 Rb Rubidium	38 Sr Strontium	39 Y Yttrium	40 Zr Zirconium	41 Nb Niobium	42 Mo Molybdenum	43 Tc Technetium	44 Ru Ruthenium	45 Rh Rhodium	46 Pd Palladium	47 Ag Silver	48 Cd Cadmium	49 In Indium

Detector pulse height distribution (PHD) window tuning

Diffraction Data – What do we get?

We call the measurement a diffraction pattern or diffractogram (not a spectrum!)

Each phase in the sample gives us a set of peaks (a “fingerprint”)

Important features:

- Background
- Peak positions
- Peak shapes
- Peak intensities

Diffraction Data – Peak positions

- Peak positions can be used to obtain:
 - d-spacings
 - Unit cell dimensions
 - Crystal class (cubic, hexagonal, etc.)
 - Possible space groups (from systematic absences)
 - Qualitative phase analysis (what's in the sample?)

XRD – Database search & match

Diffraction Data – Peak Shapes

- Peak shapes are affected by:
 - Instrument – finite source size, axial divergence, slit dimensions, detector resolution.
 - Crystallite size below ~ 100 nm – can determine size from peak broadening (Scherrer equation).
 - Microstrain – a “range” of lattice parameters due to strain. Can be isotropic or anisotropic.
 - Ordered defects – Stacking faults, antiphase boundaries.
- For quantitative analysis, a standard with no strain or size broadening must be measured.
e.g. Si, LaB_6 , Al_2O_3 , ...

Diffraction Data – Peak Intensities

- Intensity of diffraction peaks (hkl) is proportional to the square of the structure factor amplitude

$$F(hkl) = \sum_{j=1}^N f_j \exp(2\pi i(hx_j + ky_j + lz_j))$$

- Intensities give information about:
 - Positions and types of atoms
 - Site occupancy of atoms
 - Atomic displacement parameters
 - Orientation of crystallites/grains
- Use **integrated** peak intensities (area under peak)
- Accurate intensities are required for quantitative phase analysis and structure refinement.

Analysis – How do we get the information out?

- Initially, powder methods were used mainly for phase identification – “fingerprinting”
- 1966-1969: Hugo Rietveld recognised the growing power of computers in crystallography and developed a “whole pattern” fitting approach to powder diffraction.
- This overcame the problems associated with overlapping reflections.

Hugo Rietveld

The Rietveld Method

- Each data point is an observation.
- Least-squares algorithm used to obtain the best fit of the structural model to the powder pattern.
- Refinement of multiple phases and even multiple datasets is possible.
- Requires an approximate starting structure and accurate intensities.
- Parameters can be highly correlated.
- Restraints/constraints may be required for limited data.

Parameters in Rietveld Refinement

- Structural variables
 - Atom positions, fractional occupancies, atomic displacement parameters (ADPs)
(in most single crystal software, these are the only refinable parameters)
- Profile parameters
 - Background
 - Peak shape, including width and asymmetry
 - Unit cell constants
 - Wavelength
 - Diffractometer zero point
 - Sample height and displacement relative to instrument centre
- Correction terms
 - Absorption
 - Extinction
 - Surface roughness
 - Preferred orientation

Other Radiation Sources - Synchrotrons

Australian Synchrotron

- Synchrotrons are particle accelerators that use high speed electrons to produce X-rays.
- Synchrotron X-ray beams are:
 - Highly monochromatic, yielding narrow peaks
 - Tuneable in wavelength
 - Extremely intense and highly focused
- Special detectors
- Advanced sample environments
- Smaller samples possible
- Mapping of samples feasible

Other Radiation Sources - Neutrons

OPAL Reactor, ANSTO Lucas Heights

WOMBAT neutron powder diffractometer

- A neutron has a wavelength, dependent on its velocity $\lambda = h/mv$
(λ is wavelength, h is Planck's constant, m is mass and v is velocity)
- Neutrons are produced by reactor or spallation (accelerator) sources.
- Neutrons interact with the nuclei of atoms and can penetrate bulk samples and sample environments.
- Determination of magnetic structure.
- Typically neutron sources have lower intensity. Measurements take longer.
- Time-of-flight experiments are possible.

Other Radiation Sources - Neutrons

- The X-ray scattering power of atoms depends on No. of electrons in the atom and on $Q = 4\pi \sin\theta/\lambda$
- Scattering power for neutrons depends on isotope, independent of Q .

- For neutron scattering we need to consider incoherent scattering, which adds to the background.

Australian Synchrotron

How climate change is erasing the world's oldest rock art

The Challenge

Australasia is home to some of the oldest rock art motifs in the world. In tropical latitudes, due to climate change, the rock art deterioration is accelerating. **This study asked why and how can we preserve them?**

The Solution

The PD Beamline was able to identify both the rock art pigments and the salts that form destroying the art. This helped determine the mechanisms of decay

The Impact

Minimising the impacts of climate change will help preserve the incredible artworks Australasia's earliest people left to us

Australian Synchrotron

Probing the depths of the sea

The Challenge

To understand how Ni^{2+} behaves during (bio)geochemical redox cycling. This is important to gain vital information about changes in ocean circulation and ocean productivity.

The Solution

The **Powder Diffraction Beamline** is able to identify and quantify trace amounts of phases in complex mineral mixtures

The Impact

- Ni^{2+} exchanges in the presence and absence of Mn^{2+} , making metal concentrations in seawater determined from deposits unreliable
- Gain insight into ocean and climatic evolution
- Understand biogeochemical manganese cycle

Australian Synchrotron

Dolomite for low cost thermochemical energy storage

The Challenge

Increase the energy density and reduce the amount of storage material required in concentrating solar thermal power plants. This is important to lower the cost of solar energy production.

The Solution

The **Powder Diffraction** beamline is able to carry out in situ experiments to establish the phase changes and presence of trace phases that may form during reversible CO₂ absorption.

The Impact

- Lower cost
- Less material is needed
- Greater uptake in solar energy by the industrial and commercial sectors

Mined dolomite (Watheroo)

Synthetic dolomite

CO₂ methanation

MOF-derived Ru⁰/ZrO₂ catalysts

Batteries

Sodium-sulfur batteries

❖ The limited resources that are used to power our society are diminishing as the demand rises.

G20 countries' 2030 emissions targets

■ NDCs with enhanced 2030 emissions reduction targets compared to previous NDCs ■ Have not yet submitted new or updated NDCs ■ NDCs that are the same or weaker compared to previous NDCs

G20 Members	Updated 2030 reduction targets	Net-zero targets in law, policy, or pledge
Argentina	Not exceeding 359 metric tons of carbon dioxide by 2030	Net zero by 2050
Canada	40-45% below 2005 levels by 2030	Net zero by 2050
EU (incl. Italy, France and Germany)	55% below 1990 levels by 2030	Net zero by 2050
Japan	46-50% below 2013 levels by 2030	Net zero by 2050
Russia	70% of 1990 levels by 2030	No target
South Africa	Not exceeding 350-420 metric tons of carbon dioxide by 2030	No target
UK	68% below 1990 levels by 2030	Net zero by 2050
US	50-52% below 2005 levels by 2030	Net zero by 2050
Brazil	43% below 2005 levels by 2030	Net zero by 2050
Mexico	Reduce its emissions by 22% below a business-as-usual scenario by 2030, but a conditional 36% target below BAU is on the cards	No target
Australia	26-28% below 2005 level by 2030	Net zero by 2050
Indonesia	29% reduction and conditional reduction up to 41% by 2030	No target
South Korea	30% below 2017 level by 2030	Net zero by 2050
China	Previous target: 60-65% carbon intensity reduction below 2005 level by 2030	Net zero by 2060
India	Previous target: 33-35% emissions intensity reduction below 2005 by 2030	No target
Saudi Arabia	Previous target: Actions only	Net zero by 2060 (excluding exports)
Turkey	Previous target: 21% by 2030	Net zero by 2053

We live in the real world:

- ✓ Carbon neutrality and renewable energy
- ✓ Efficient energy storage solutions
- ✓ Portable tech and electric vehicles (EVs)
- User community growth of ~ 500% over past 5 years of beamline operations

SCIENCE ADVANCES Vol 4, Issue 6 (2018)

TOOL CHEST	XAS	MEX (new in 2022)	PD	ADS (ca. 2024)
Capability	✓ Valence states ✓ Atomic structure		✓ Crystalline structure ✓ Phase composition	✓ Add imaging
Energy range	5 – 31 keV	1.8 – 14 keV	5.5 – 22 keV	50 – 150 keV
Resolution	0.2 eV	< 0.1 eV (HERFD)	Monochromatic	Monochromatic, pink, and white
Beam size	0.25 x 5 mm	2 x 10 mm, or μm	0.8 x 1 mm to 1 x 5 mm	10x50μm - 15x15mm
Experimental stations	Both beamlines have two stations; incl standard XAS station suited for batteries		Two stations; incl high throughput station for batteries	Three stations; incl station suited to fast battery work (msec)
Detection limit	< 100 ppm (XANES)		0.2 wt.%	
Scan speed	20 min (XANES) 3 min (slew scan, 2022)		Few seconds	
Automation	Batch scanning ex-situ samples		Robot automation for capillary samples, batch scanning coin cells	

Powder Diffraction (PD)

✓ Multiple *in-situ* battery sample holders

Use PD to determine:

- Crystalline structure
- Phase composition
- ✓ Determine long and short range order of structures in solid state materials

✓ Automatic *ex-situ* robotic sample change over

- ✓ Synchrotron PD provides the most sensitive detection of crystalline phases
- ✓ High throughput and fast measurement time allows more specimens
- ✓ Synchrotron PD provides a gold standard for this well established technique

X-ray Absorption Spectroscopy (XAS)

- ✓ Efficient *ex-situ* loading and batch scanning
- ✓ *In-situ* battery sample holder available

Use XAS to determine:

- Valence states via XANES
- Local atomic structure via EXAFS

- ✓ Independent of structure and size: nanoparticles, single atoms, and amorphous materials are fine.

Prussian Blue Analogues (PBAs)

Prussian Blue has been studied since 1978 for its application in electrochemical energy storage and conversion. However, replacing some Fe metal centres with other metal ions (Mn, Co, Ni, etc) to form analogous materials have recently resulted in markedly more efficient materials. For example, Mn centred PBAs:

- Stabilizes the structure -> excellent cycle lifespan
- Eliminates dissolution of the active Mn^{2+} ions
- 80% capacity retention over 300 cycles
- High energy density
- Can be mass produced
