Stability and Surface Reconstruction of Bi₂Se₃ on Exposure to Atmosphere

Thursday, 20 November 2014 13:30 (30 minutes)

The new class of topological materials including Bi₂Se₃ offer opportunities to develop next generation electron devices that utilize spin generation and detection without ferromagnetism [1]. However, the fate of the Bi₂Se₃ surface upon exposure to atmosphere remains unclear. In particular whilst the topology of Bi₂Se₃ guarantees the presence of a metallic surface, the topological properties of the metallic surface depend on the surface and its reconstruction [2]. Therefore, it is essential to understand the structure of the air-exposed Bi₂Se₃ surface in order to interpret the properties of any air-exposed Bi₂Se₃ device.

Utilizing high-resolution surface sensitive XPS we reveal that five minute air exposure causes a drastic change to the surface of in-situ cleaved Bi₂Se₃. An additional component within the Bi 5d core level was observed after exposure that corresponds to the formation of isolated ~0.8 nm thick Bi₂ layers at the surface of Bi₂Se₃ [3]. This Bi₂ layer is found to occur across multiple samples and is precipitated rapidly by exposure to atmosphere, while samples left for several days in UHV after in-situ cleaving show no change. This finding offers new avenues to study a 2D TI (Bi₂) interfaced with a 3D TI (Bi₂Se₃) but also has significant consequences in understanding the electronic structure of air-exposed Bi₂Se₃.
